Assessing the trophic status of Lake Mikri Prespa, Greece

T.S. Koussouris
A.C. Diapoulis
E.T. Balopoulos

Keywords: Trophic status, modelling, lake, Greece.

Lake Mikri Prespa is a shallow water basin characterized by unstable thermal stratification, primary dimictic conditions and clinograde distribution of dissolved oxygen.

The nutrient concentrations are high, indicating a trend towards eutrophication. Total phosphorus input calculated on the basis of the export coefficient accounting for land-uses and other sources is estimated to be of the order of $15 \times 10^6$ kg yr$^{-1}$. A mathematical model is applied to assess the trophic status of Lake Mikri Prespa in the light of development projects recently undertaken in its catchment area. Evaluation of the trophic status reveals that the critical and permissible loading for Lake Mikri Prespa are 0.07 and 0.03 gm$^{-2}$y$^{-1}$, respectively. Present loading of the lake is estimated at 0.27 gm$^{-2}$y$^{-1}$ indicating that the lake is already at a dangerous level. On the basis of the employed O.E.C.D. relationships, Lake Mikri Prespa is presently classified as mesotrophic to eutrophic.

1. Introduction

During the last decades various development projects, mainly intensified agricultural practices, have not only threatened the natural environment but also altered directly or indirectly the trophic situation of Lake Mikri Prespa (Koussouris & Diapoulis 1983, Newbold 1986). This lake is considered to be an internationally important wetland offering valuable sites for waterfowl, where rare and threatened species such as pelicans, cormorants, egrets, herons etc. occur (e.g. Terrasse et al. 1969, Pyrovetsi et al. 1984, Katsadorakis 1986). The ecologically diversified fauna and flora, as well as the luxuriant aquatic vegetation, the extensive marshes, the floating islets of thick reed clusters, the wet meadows and the lake itself make Lake Mikri Prespa a rich wildlife area.

Recent limnological investigations carried out by the National Centre for Marine Research, Department of Inland Waters have provided information on the morphological characteristics of the lake and its nutrient conditions (Tables I, II).

This article deals with a hydrobiological analysis of the lake, an estimation of nutrient loading and finally with the application of a mathematical model for the evaluation of its trophic status on the basis of an analysis of the total phosphorus input.

2. Description of the area

Lake Mikri Prespa lies on the Greek-Albanian border in Macedonia, Greece (40°45'N -21°06'E) at 853.5 m. above sea level, has a surface of 53 km², a maximum depth of 8.4 m. and a mean depth of 4.1 m. The lacustrine system is within a small catchment area of 207 km², consisting geologically of carbonate rock (63 %), quaternary formations (19 %), igneous rock (12 %) and metamorphic rock (6 %) (I.G.M.E. 1983). (Fig. 1).

The lake is supplied with water only seasonally through surface runoff from a number of small creeks, torrents and from irrigation and also probably through seepage and underground sources. The lake has a natural outflow to lake Megali Prespa, as well as into fissures in the underground.

The usage of the lake water is mainly for irrigation (8.5 x 10⁶m³y⁻¹) with increasing demands each year, for 17.4 km² of intensity cultivated land. The lake is also used for commercial fishery. Especially the fish catches and their species composition have reduced dramatically during the last two decades from 450 tons in 1964 to 50 tons in 1983 (Koussouris & Diapoulis 1983).

The watershed area is mostly covered by deciduous oak and beech forest (72.4 %) with increasing timber-felling activities. The rest of the land is mainly used for pasturing (18.2 %) and agriculture (8.4 %), from which 7.5 km² is irrigated with lake...
The most pronounced features of the lake environment are:

— the extensive reed belt surrounding the lakeshore;

— the organic matter produced mainly by reeds that contributes to the nutrient loading of the lake;

— the agricultural runoff and the increasing soil erosion that accelerate the trophic conditions of the lake;

— the richness and importance of its avifauna.

According to data from the National Meteorological Service (1965-1985) the climatic regime of the area could be characterized as semi-humid to humid with mesothermal conditions. Mean annual air temperature (average of 20 years) is 11.3° C (range 1.4 - 21.6° C). The mean annual precipitation is 610 mm on the lake and 667 mm on the watershed (Fig. 2). The remaining meteorological parameters, in annual mean values are:

— evaporation, 681 mm;
— evapotranspiration, 457 mm;
— potential evapotranspiration, 689 mm;
— relative humidity, 63.4 %;
— main wind direction, N-W.
3. Hydrological analysis

To evaluate the present level of the trophic status of Lake Mikri Prespa the annual hydrological budget has been established. Morphometry, climate and nutrient loading do not vary significantly from year to year. Therefore, it may be assumed that the water budget of the lake is in a steady state. The simplified annual hydrological balance of the lake can be adequately described by Ward's (1975) formula:

\[ \text{PL} + \text{R} + \text{GL} = \text{E}_a + \text{Q} + \text{IR} \] (1)

where:

- \( \text{PL} \) = the precipitation volume on the lake,
- \( \text{R} \) = lateral flow and surface runoff,
- \( \text{GL} \) = total underground inflow to the lake,
- \( \text{E}_a \) = evaporation volume of the lake,
- \( \text{IR} \) = the irrigation water volume from the lake,
- \( \text{Q} \) = the surface outflow from the lake plus the underground seepages from the lake.

According to Ward's (1975) analysis, \( \text{R} \) and \( \text{GL} \) depend on climatic and physiographic parameters, of which geological structure of the rocks constitutes the decisive factors of the watershed area. However, \( \text{R} \) and \( \text{GL} \) may also be calculated by the following formulae:

\[ \text{R} = c \times A_t \times P_r \] (2)
\[ \text{GL} = C_l \times A_l \times P_l \] (3)

where:

- \( c \) = the actual runoff coefficient (~0.20)
- \( A_t \) = the terrestrial area
- \( P_r \) = the precipitation on the terrestrial area
- \( C_l \) = the total infiltration coefficient of the area (see Table III)

Substituting the numerical values of \( c, A_t, P_r, A_l, C_l, E_r, \text{IR}_a \) from Tables I and II and subsequently \( \text{R} \), \( \text{GL} \), \( \text{PL} \), \( E_a \), and \( \text{IR} \) in Equation (1) results that the total outflow from the lake is:

\[ \text{Q} = 65 \times 10^6 \text{m}^3 \] (7)

Then, other hydrological parameters, like the areal water load (hydraulic load) (8), the hydraulic retention time (residence time) (9) and the renewal time (10) may be estimated by the following formulae, substituting the total outflow from the lake (Q) and total inflows to the lake (\( \text{I}_n = \text{R} + \text{GL} \)) from equation (7) and formula (1), while and \( V \) and \( A_l \) from Table 1:

\[ \text{sq} = \frac{Q}{A_l} \] (8)
\[ t = \frac{V}{Q} \] (9)
\[ r = \frac{V}{\text{I}_n} \] (10)

where:

- \( V \) = lake volume
- \( \text{I}_n \) = inflow into the lake

4. Trophic situations-nutrient loadings

Lake Mikri Prespa, because of its shallowness has an unstable thermal stratification, although dimictic situations primarily occur every 2-3 years, when ice covers the lake for a few weeks. In calm summer conditions the unstable thermocline starts from 1.0 m. depth and reaches 4.5 m.

The water temperatures ranges (Koussouris & Diapoulis 1983) between:

8.8-11.1° C during the spring;  
18.3-28.1° C during the summer;  
18.7-22.5° C during the fall;  
4.0-12.4° C during the winter.

The various water quality variables are given in Table II with their averages and ranges. The lake water is moderately hard and turbid with buffering capacity (between 1.7 - 3.0 meq l⁻¹) and is well oxygenated, except a layer near to bottom during short periods and in a few sites (0.1 - 4.8 p.p.m.). Ammonia does not remain bellow the 20 \( \mu g \) l⁻¹ N.NH₄⁺ standard, while nitrate may exceed the 60 \( \mu g \) l⁻¹ N.NO₃⁻. Nitrates range from 0.6-6.2 \( \mu g \) l⁻¹, phosphates from 2.8-22.0 \( \mu g \) l⁻¹ and total phosphorus from 9.0-42.0 \( \mu g \) l⁻¹.

For the evaluation of the trophic status in Lake Mikri Prespa it is useful to compare values of Table II, that contains published and unpublished data, with Wetzel's (1983) suggestion that the N/P ratio for optimal algal growth is 7/1 by weight. The fact that in Lake Mikri Prespa this ratio usually fluctuates between 3.2 and 41.1, with 16.1 as mean value during the mixing period of water, indicates that phosphorus is the limiting nutrient for algal growth.

Furthermore the concentration of dissolved phosphate has been compared with the presence of some algal taxa. The measurements indicate that there is algal activity, mainly from chlorophyceae (Elakatothrix gelatinosa Wille, Scenedesmus quadricauda Turp.em.Chod., Selenastrum gracilis Reinsch) and bacillariophyceae (Cyclotella ocellata Pant, C. meneghianiana Kutz, Nitzschia holsatica Hust, and Navicula gracilis Ehr) during spring, when the concentration of o-P ranges from 4.0 to 5.2 \( \mu g \) l⁻¹ (4.6 \( \mu g \) l⁻¹ mean value). During summer period, when the dominating groups are chlorophyceae (Closterium gracile Bred., Selenastrum hibriaunum Reinsch, Scenedesmus quadricauda Turp.em.Chod.), bacillariophyceae (Cyclotella ocellata Pant. Melosira granulata (Ehr) Ralfs and Navicula cryptocephala Kütz) and cyano-
phyceae (Chroococcus limneticus v. distans G.M. Smith, Aphanocapsa pulchra (Kük) Rabh, Microcystis flos-aquae (Wittr.) Kirchn., M. aeruginosa Kütz) the o-P ranges from 8.0 to 10.5 μg l⁻¹ (9.3 μg l⁻¹ mean value). The same values of o-P are found until late September and algal blooms remain present. Under certain meteorological conditions (high temperatures, little to no rainfall, high evaporation rates etc.), Lake Mikri Prespa may have such a high biomass that its decay might cause deficiency of dissolved oxygen and phosphate enrichment in the hypolimnion (Koussouris & Salmadjis 1987).

5. The model

Evaluation of the trophic status can be done by several nutrient loading models (e.g. Vollenweider 1975, Dillon et al. 1974, Kirchner et al. 1975). The Dillon et al. model was used to consider the balance of total phosphorus in the Lake Mikri Prespa. The model assumes the lake to be homogenous completely mixed and at steady state. The model showed that the total nutrient concentration in surface water is directly proportional to the nutrient loading.

\[ L (1-R) t = Z \times N \]

where:

- \( L = \text{Areal nutrient loading, g m}^{-2}\text{y}^{-1}, \)
- \( R = \text{Fraction of nutrient retained in the lake} \)
- \( t = \text{Hydraulic retention time (t = V/Q = 3.4 years)} \)
- \( Z = \text{Mean depth (Z = 4.1 meters)} \)
- \( N = \text{Total nutrient concentration in lake, (0.028 g m}^{-3} (\text{mg l}^{-1}). \)

Calculated in this way, the loading of phosphorus appeared to be 0.28 g m²y⁻¹ or about 15000 kg y⁻¹ for the lake surface.

The nutrient loading into a lake can be estimated among other methods by using export coefficients given by Rast & Lee (1983) and Tomps Corp. (1974). Phosphate enters the lake basin from many sources such as, atmospheric fallout and precipitation, runoff by land-use, septic tanks of the rural area and the excreta of livestock and avifauna.

Based on these coefficients the Lake Mikri Prespa received a phosphorus loading of about 15.0 X 10⁶ g y⁻¹.

Table IV. Estimation of phosphorus inputs in Lake Mikri Prespa according to export coefficient factors vs. land-uses and other sources (* Rast & Lee, 1983 and ** Tomps corp., 1974).

**TOTAL INPUT OF PHOSPHORUS \times 10^6, g y⁻¹**

14.51

Key: \( P_{ex} = \text{Phosphorus export coefficient} \)
- \( F = \text{Factor} \)
- \( P_L = \text{Phosphorus loading}. \)
(see Table III). Assuming that 100% of the above loading reaches the lake, the surface loading becomes above 0.2 g m⁻² y⁻¹.

Of the above 15000 kg y⁻¹ loading, only 2000 kg y⁻¹ will leave the system in the outflow and the rest (about 13000 kg y⁻¹) will sedimented.

Based on Vollenweider's (1976) critical loading relationships of phosphorus for a lake with mean depth less than five meters (Lₜ/qₛ = (10-20)(1 + t)), the critical loading for Lake Mikri Prespa should be 0.07 g m⁻² y⁻¹ and the permissible loading 0.03 g m⁻² y⁻¹ (Fig. 3). Consequently the lake can be classified as meso- to eutrophic (O.E.C.D.) while a loading of 0.27 g m⁻² y⁻¹ (Fig. 3) is near the dangerous level.

If however the proposed development projects of the area take place, through the intensified agricultural practice and the operation of the new hatchery, the expected enrichment of the lake water could affect the lake's ecosystem and might be devastating during drought.
